

## Solutions to HW 10

---

- (1) (Sec 6.2 Problem 21)(30 pts)  $y'' - 2y' + 2y = \cos(t)$ .  $y(0) = 1$ ,  $y'(0) = 0$

Taking the Laplace's transform of the differential equation

$$y'' - 2y' + 2y = \cos(t), \text{ we have}$$

$$L(y'' - 2y' + 2y) = L(\cos(t)) = \frac{s}{s^2+1}. \text{ Using } L(y'') = s^2L(y) - sy(0) - y'(0) \text{ and}$$

$$L(y') = sL(y) - y(0), \text{ we have}$$

$$s^2L(y) - sy(0) - y'(0) - 2(sL(y) - y(0)) + 2L(y) = \frac{s}{s^2+1} \text{ and}$$

$$(s^2 - 2s + 2)L(y) - sy(0) - y'(0) + 2y(0) = \frac{s}{s^2+1}.$$

Substituting  $y(0) = 1$  and  $y'(0) = 0$ , we have

$$(s^2 - 2s + 2)L(y) - s + 2 = \frac{s}{s^2+1} \text{ and}$$

$$(s^2 - 2s + 2)L(y) = s - 2 + \frac{s}{s^2+1}.$$

$$\text{So } L(y) = \frac{s-2}{s^2-2s+2} + \frac{s}{(s^2-2s+2)(s^2+1)}.$$

Note that  $s^2 - 2s + 2 = (s - 1)^2 + 1$ . First, we simplify the term by noting that

$$\frac{s-2}{s^2-2s+2} = \frac{s-2}{(s-1)^2+1} = \frac{-1}{(s-1)^2+1} + \frac{3}{(s-1)^2+1}.$$

Now we simplify the term  $\frac{s}{(s^2-2s+2)(s^2+1)}$  by partial fraction. We have

$$\frac{s}{(s^2-2s+2)(s^2+1)} = \frac{s}{((s-1)^2+1)(s^2+1)} = \frac{a(s-1)+b}{(s-1)^2+1} + \frac{cs+d}{s^2+1}. \text{ Multiplying } ((s-1)^2+1)(s^2+1),$$

we have

$$s = (a(s-1) + b)(s^2 + 1) + (cs + d)((s-1)^2 + 1)$$

$$= (as + (-a + b))(s^2 + 1) + (cs + d)(s^2 - 2s + 2)$$

$$= as^3 + (-a + b)s^2 + as + (-a + b) + cs^3 + ds^2 - 2cs^2 - 2ds + 2cs + 2d$$

$$= (a + c)s^3 + ((-a + b) + d - 2c)s^2 + (a - 2d + 2c)s + (-a + b + 2d). \text{ Comparing the}$$

coefficient, we get  $a + c = 0$ ,  $-a + b + d - 2c = 0$ ,  $a - 2d + 2c = 1$  and  $-a + b + 2d = 0$ .

From  $a + c = 0$ , we have  $c = -a$ ,  $a + b + d = 0$ ,  $-a - 2d = 1$  and  $-a + b + 2d = 0$ .

Multiplying  $-1$  to  $a + b + d = 0$ , we get  $-a - b - d = 0$ . Adding  $-a + b + 2d = 0$ ,

we have  $-2a + d = 0$ . Using  $-a - 2d = 1$  and  $-2a + d = 0$ , we have  $a = -\frac{1}{5}$  and

$d = -\frac{2}{5}$ . From  $a + b + d = 0$  and  $c = -a$ , we get  $b = -a - d = \frac{3}{5}$  and  $c = \frac{1}{5}$ . Hence

$$\frac{s}{(s^2-2s+1)(s^2+1)} = -\frac{1}{5} \frac{(s-1)}{(s-1)^2+1} + \frac{3}{5} \frac{1}{(s-2)^2+1} + \frac{1}{5} \frac{s}{s^2+1} - \frac{2}{5} \frac{1}{s^2+1}.$$

$$\text{From } L(y) = \frac{s-2}{s^2-2s+2} + \frac{s}{(s^2-2s+2)(s^2+1)},$$

$$\frac{s-2}{s^2-2s+2} = \frac{s-1}{(s-1)^2+1} + \frac{-1}{(s-1)^2+1} \text{ and}$$

$$\frac{s}{(s^2-2s+1)(s^2+1)} = -\frac{1}{5} \frac{(s-1)}{(s-1)^2+1} + \frac{3}{5} \frac{1}{(s-2)^2+1} + \frac{1}{5} \frac{s}{s^2+1} - \frac{2}{5} \frac{1}{s^2+1}, \text{ we get}$$

$$L(y) = \frac{4}{5} \frac{(s-1)}{(s-1)^2+1} - \frac{2}{5} \frac{1}{(s-1)^2+1} + \frac{1}{5} \frac{s}{s^2+1} - \frac{2}{5} \frac{1}{s^2+1} \text{ and}$$

$$y(t) = \frac{4}{5} e^t \cos(t) - \frac{2}{5} e^t \sin(t) + \frac{1}{5} \cos(t) - \frac{2}{5} \sin(t).$$

- (2) (Sec 6.2 Problem 23)(30 pts)  $y'' + 2y' + y = 4e^{-t}$   $y(0) = 2$ ,  $y'(0) = -1$

Taking the Laplace's transform of the differential equation  $y'' + 2y' + y = 4e^{-t}$ ,

we have  $L(y'' + 2y' + y) = L(4e^{-t})$ . Using  $L(y'') = s^2L(y) - sy(0) - y'(0)$ ,  $L(y') =$

$$sL(y) - y(0) \text{ and } L(4e^{-t}) = 4L(e^{-t}) = \frac{4}{s+1}, \text{ we have}$$

$$s^2L(y) - sy(0) - y'(0) + 2(sL(y) - y(0)) + L(y) = \frac{4}{s+1} \text{ and}$$

$$(s^2 + 2s + 1)L(y) - sy(0) - y'(0) - 2y(0) = \frac{4}{s+1}.$$

Substituting  $y(0) = 2$  and  $y'(0) = -1$ , we have

$$(s^2 + 2s + 1)L(y) - s \cdot 2 - (-1) - 2 \cdot 2 = \frac{4}{s+1} \text{ and } (s^2 + 4s + 4)L(y) = \frac{4}{s+1} + 2s + 3.$$

Note that  $s^2 + 2s + 1 = (s + 1)^2$ . So we have  $(s + 1)^2 L(y) = \frac{4}{s+1} + 2s + 3$  and  $L(y) = \frac{4}{(s+1)^3} + \frac{2s+3}{(s+1)^2}$ . We can simplify  $\frac{2s+3}{(s+1)^2}$  by substituting  $u = s + 1$ ,  $s = u - 1$  and  $\frac{2s+3}{(s+1)^2} = \frac{2(u-1)+3}{u^2} = \frac{2u+1}{u^2} = \frac{2}{u} + \frac{1}{u^2} = \frac{2}{s+1} + \frac{1}{(s+1)^2}$ .

Hence we have  $L(y) = \frac{4}{(s+1)^3} + \frac{2}{(s+1)} + \frac{1}{(s+1)^2}$  and

$$y = L^{-1}\left(\frac{4}{(s+1)^3} + \frac{2}{(s+1)} + \frac{1}{(s+1)^2}\right).$$

$$\text{Using } L(e^{-t}) = \frac{1}{s+1}, L(te^{-t}) = \frac{1}{(s+1)^2}, \text{ and } L(t^2e^{-t}) = \frac{2}{(s+1)^3},$$

$$\text{we have } L^{-1}\left(\frac{1}{s+1}\right) = e^{-t}, L^{-1}\left(\frac{1}{(s+1)^2}\right) = te^{-t} \text{ and } L^{-1}\left(\frac{1}{(s+1)^3}\right) = \frac{t^2e^{-t}}{2}.$$

Therefore

$$\begin{aligned} y &= L^{-1}\left(\frac{4}{(s+1)^3} + \frac{2}{(s+1)} + \frac{1}{(s+1)^2}\right) \\ &= 4 \cdot \frac{t^2e^{-t}}{2} + 2e^{-t} + te^{-t} = 2t^2e^{-t} + 2e^{-t} + te^{-t}. \end{aligned}$$

(3) (Sec 6.3 Problem 8)(15 pts)

$$f(t) = \begin{cases} 0, & 0 \leq t < 1, \\ t^2 - 2t + 2, & 1 \leq t. \end{cases}$$

We have  $f(t) = (t^2 - 2t + 2)u_1(t)$ . Let  $g(t - 1) = t^2 - 2t + 2 = (t - 1)^2 + 1$ . Then  $g(t) = g((t + 1) - 1) = t^2 - 1$  and  $f(t) = u_1(t)g(t - 1)$ . Hence  $L(f(t)) = L(u_1(t)g(t - 1)) = e^{-s}L(g(t)) = e^{-s}L(t^2 + 1) = e^{-s}\left(\frac{2}{s^3} + \frac{1}{s}\right)$ .

(4) (Sec 6.3 Problem 9)(15 pts)

$$f(t) = \begin{cases} 0, & 0 \leq t < \pi, \\ t - \pi, & \pi \leq t < 2\pi, \\ 0, & 2\pi \leq t. \end{cases}$$

We have  $f(t) = (t - \pi)u_{\pi, 2\pi}(t) = (t - \pi)(u_{\pi}(t) - u_{2\pi}(t)) = (t - \pi)u_{\pi}(t) - (t - \pi)u_{2\pi}(t)$ . Let  $g(t - \pi) = t - \pi$  and  $h(t - 2\pi) = t - \pi$ . Then  $g(t) = g((t + \pi) - \pi) = t$ ,  $h(t) = h((t + 2\pi) - 2\pi) = t + 2\pi - \pi = t + \pi$  and  $f(t) = u_{\pi}(t)g(t - \pi) - u_{2\pi}(t)g(t - 2\pi)$ . Hence  $L(f(t)) = L(u_{\pi}(t)g(t - \pi) - u_{2\pi}(t)h(t - 2\pi)) = e^{-\pi s}L(g(t)) - e^{-2\pi s}L(h(t)) = e^{-\pi s}L(t) - e^{-2\pi s}L(t + \pi) = e^{-\pi s}\frac{1}{s^2} - e^{-2\pi s}\left(\frac{1}{s^2} + \pi\frac{1}{s}\right)$ .

(5) (Sec 6.3 Problem 10)(10 pts)  $f(t) = u_1(t) + 2u_2(t) - 6u_4(t)$ .  $L(f(t)) = L(u_1(t) + 2u_2(t) - 6u_4(t)) = L(u_1(t)) + 2L(u_2(t)) - 6L(u_4(t)) = \frac{e^{-s}}{s} + 2\frac{e^{-2s}}{s} - 6\frac{e^{-4s}}{s}$ .
